# More on the Intuitionistic Borel Hierarchy 

Takayuki Kihara<br>Nagoya University, Japan

CCC 2023: Continuity, Computability, Constructivity, From Logic to Algorithms, Kyoto, Japan, September 27, 2023

In classical theory, the following result is well known:
The set of all eventually zero sequences is $\boldsymbol{\Sigma}_{\mathbf{2}}^{\mathbf{0}}$-complete.

- i.e., $F I N=\left\{x \in \mathbb{N}^{\mathbb{N}}: \exists n \forall m>n . x(m)=0\right\}$ is $\Sigma_{2}^{0}$-complete.

Here, for $\boldsymbol{A}, \boldsymbol{B} \subseteq \mathbb{N}^{\mathbb{N}}$ :

- $\boldsymbol{A}$ is reducible to $\boldsymbol{B}$ (written $\boldsymbol{A} \leq \boldsymbol{B}$ ) iff
$\exists$ continuous $\varphi \forall x(x \in A \Longleftrightarrow \varphi(x) \in B)$
- $\boldsymbol{A}$ is $\boldsymbol{\Gamma}$-complete if $\boldsymbol{A}$ is a s-greatest element among $\boldsymbol{\Gamma}$ sets.

The same result holds if "continuous" is changed to "computable".
$\Sigma_{2}^{0}$-completeness of $\boldsymbol{F I N}$ is "trivial" to those of us familiar with classical theory, but it is not necessarily true in intuitionistic mathematics.

## Theorem (Veldman 2008)

In a certain intuitionistic system,
$\boldsymbol{F I N}=\left\{\boldsymbol{x} \in \mathbb{N}^{\mathbb{N}}: \exists \boldsymbol{n} \forall \boldsymbol{m}>\boldsymbol{n} . \boldsymbol{x}(\boldsymbol{m})=\mathbf{0}\right\}$ is not $\boldsymbol{\Sigma}_{2}^{0}$-complete.

- One of the key intuitionistic principles assumed by Veldman is Brouwer's continuity principle.
- The details of Veldman's assumptions are not explained here.

Veldman also showed other results that contradict those in the classical theory.

## Theorem (Veldman 2022)

In a certain intuitionistic system, the set of (the codes of) trees which are ill-founded w.r.t. the Kleene-Brouwer ordering is not $\Sigma_{1}^{1}$-complete.

## Objective

- We clarify that Veldman's results are valuable not only in intuitionistic mathematics, but also in classical math.
- Veldman's results can be understood as results about "Levin reducibility" in classical math.
- Further refine Veldman's results using techniques in classical math.
$\triangleright$ Veldman's insights provide a new refinement to the classical arithmetical/Borel hierarchy.

What is "Levin reducibility"?

- Introduced by Leonid Levin in 1973.
- Levin's 1973 paper is a monumental paper in complexity theory that showed NP-completeness of SAT, but what Levin was really dealing with was "Levin reducibility" between search problems.
- A search problem is a binary relation $R \subseteq \Sigma^{*} \times \Sigma^{*}$.
- Any $y$ satisfying $R(x, y)$ is called a witness for $x \in|R|$, where $|R|=\{x: \exists y R(x, y)\}$.

## Definition (Levin 1973)

For a complexity class $C$ and search problems $\boldsymbol{A}$ and $\boldsymbol{B}$, $\boldsymbol{A}$ is $\boldsymbol{C}$-Levin reducible to $\boldsymbol{B}$ if there exist $\boldsymbol{C}$-functions $\varphi, \boldsymbol{\ell}, \boldsymbol{r}$ such that for any $\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{z} \in \Sigma^{*}$ the following holds:
(1) $x \in|A|$ if and only if $\varphi(\boldsymbol{x}) \in|\boldsymbol{B}|$.
(2) If $y$ is a witness for $x \in|A|$ then $r(x, y)$ is a witness for $\varphi(x) \in|\boldsymbol{B}|$.
(3) If $z$ is a witness for $\varphi(x) \in|\boldsymbol{B}|$ then $\ell(x, z)$ is a witness for $\boldsymbol{x} \in|\boldsymbol{A}|$.

- $\varphi$ is a reduction for $|\boldsymbol{A}| \leq|\boldsymbol{B}|$
- $r$ is a realizer for " $x \in|A| \Longrightarrow \varphi(x) \in|B|$ "
- $\ell$ is a realizer for " $x \in|A| \Longleftarrow \varphi(x) \in|B|$ "

The "standard model" of intuitionistic math that satisfies Veldman's assumptions would be those based on Kleene's second algebra $\boldsymbol{K}_{\mathbf{2}}$.

Thee main "algebras" ( $\mathbb{A}, \mathbb{A}_{e f f}, *$ ):

- Kleene's first algebra $K_{1}$
$\triangleright$ The algebra of computability on natural numbers.
$\triangleright \mathbb{A}=\mathbb{A}_{\text {eff }}=\mathbb{N}$ and $e * x=\varphi_{e}(x)$
$\triangleright$ where $\varphi_{e}$ is the $e$ th partial computable function on $\mathbb{N}$.
- Kleene's second algebra $\boldsymbol{K}_{2}$
$\triangleright$ The algebra of continuity on infinite strings.
$\triangleright \mathbb{A}=\mathbb{A}_{\text {eff }}=\mathbb{N}^{\mathbb{N}}$, and $e * x=\psi_{e}(x)$
$\triangleright$ where $\psi_{e}$ is the partial continuous function on $\mathbb{N}^{\mathbb{N}}$ coded by $\boldsymbol{e}$.
- Kleene-Vesley algebra $\boldsymbol{K} \boldsymbol{V}$
$\triangleright$ The algebra of computability on infinite strings.
$\triangleright \mathbb{A}=\mathbb{N}^{\mathbb{N}}, \mathbb{A}_{\text {eff }}=$ computable strings, and $e * x=\psi_{e}(x)$

Let ( $\mathbb{A}, \mathbb{A}_{\text {eff }}, *$ ) be a relative pca, i.e, $\boldsymbol{K}_{1}, \boldsymbol{K}_{2}, \boldsymbol{K} V$ or so.

- An represented space is a pair of a set $\boldsymbol{X}$ and a partial surjection $\delta: \subseteq \mathbb{A} \rightarrow X$.
$\triangleright$ If $\delta(p)=x$ then $p$ is called a name of $\boldsymbol{x} \in \boldsymbol{X}$.
- A function $f: X \rightarrow \boldsymbol{Y}$ is realizable if there exists $\boldsymbol{a} \in \boldsymbol{A}_{\text {eff }}$ such that if $\boldsymbol{p}$ is a name of $\boldsymbol{x} \in \boldsymbol{X}$ then $\boldsymbol{a} * \boldsymbol{p}$ is a name of $f(x) \in \boldsymbol{Y}$

A represented space is also known as a modest set.

- Fact: The category of represented spaces and realizable functions is a locally cartesian closed category with NNO, whose internal logic corresponds to the realizability interpretation.
- The standard model of intuitionistic mathematics satisfying Veldman's assumptions would be the category $\operatorname{Rep}\left(\boldsymbol{K}_{2}\right)$ of $\boldsymbol{K}_{2}$-represented spaces (or the realizability topos $\boldsymbol{R T}\left(\boldsymbol{K}_{\mathbf{2}}\right)$ over $\boldsymbol{K}_{\mathbf{2}}$ ).

In the category of represented spaces:

- A formula is interpreted as something like a "witness-search problem (or a realizer-search problem)"

Example: The type $\mathbb{N}^{\mathbb{N}}$ formula " $\varphi(x) \equiv \exists n \forall m \geq n . x(m)=0$ " is interpreted as a subobject $F I N \mapsto \mathbb{N}^{\mathbb{N}}$ such that

- the underlying set is $\left\{x \in \mathbb{N}^{\mathbb{N}}: \exists \boldsymbol{n} \forall \boldsymbol{m} \geq \boldsymbol{n} . \boldsymbol{x}(\boldsymbol{m})=\mathbf{0}\right\}$
- a name of $\boldsymbol{x} \in \boldsymbol{F I N}$ is a pair of $\langle\boldsymbol{x}, \boldsymbol{n}\rangle$, where $\boldsymbol{n}$ is an existential witness.

Fact: Every subobject of $\boldsymbol{X}$ has a representative of the following form:

- an underlying set $\boldsymbol{A}$ is a subset of $\boldsymbol{X}$
- a name of $\boldsymbol{x} \in \boldsymbol{A}$ is the pair of a name $\boldsymbol{p}$ of $\boldsymbol{x} \in \boldsymbol{X}$ and some $\boldsymbol{q} \in \mathbb{A}$. This $\boldsymbol{q}$ is considered as a "witness".

Roughly speaking:

- A subobject is a subset with witnesses.
- A regular subobject is a subset without witnesses.

Recall: for $\boldsymbol{A}, \boldsymbol{B} \subseteq \mathbb{N}^{\mathbb{N}}, \boldsymbol{A}$ is reducible to $\boldsymbol{B}$ (written $\boldsymbol{A} \leq \boldsymbol{B}$ ) iff $\exists$ continuous $\varphi \forall x(x \in A \Longleftrightarrow \varphi(x) \in B)$
That is, $\boldsymbol{A}=\boldsymbol{\varphi}^{-1}[\boldsymbol{B}]$.
Its categorical version would be something like:
Def: Let $\boldsymbol{X}, \boldsymbol{Y}$ be objects in a category $\boldsymbol{C}$ having pullbacks.
A mono $\boldsymbol{A} \stackrel{\alpha}{\mapsto} X$ is reducible to $\boldsymbol{B} \stackrel{\beta}{\mapsto} \boldsymbol{Y}$ if $\boldsymbol{A} \stackrel{\alpha}{\mapsto} X$ is a pullback of $\boldsymbol{B} \stackrel{\beta}{\mapsto} \boldsymbol{Y}$ along some morphism $\varphi: X \rightarrow Y$.

When this notion is interpreted in the category of represented spaces, we obtain (computable/continuous) Levin reducibility.

A subobject $\boldsymbol{A} \mapsto \boldsymbol{X} \approx$ a subset with witnesses:

- an underlying set $\boldsymbol{A}$ is a subset of $\boldsymbol{X}$
- a name for $\boldsymbol{x} \in \boldsymbol{A}$ is a pair of a name $\boldsymbol{x} \in \boldsymbol{X}$ and a witness.

For subobjects $\boldsymbol{A}, \boldsymbol{B} \mapsto \boldsymbol{X}, \boldsymbol{A}$ is Levin reducible to $\boldsymbol{B}$ if there exist a morphism $\varphi: X \rightarrow X$ and realizable functions $\ell, r$ such that for any $\boldsymbol{x}, \boldsymbol{y}, \boldsymbol{z}$ the following holds:
(1) $x \in \boldsymbol{A}$ if and only if $\varphi(\boldsymbol{x}) \in \boldsymbol{B}$.
(2) If $\dot{x}$ is a name of $\boldsymbol{x} \in \boldsymbol{X}$ and $\dot{y}$ is a name of witness for $\boldsymbol{x} \in \boldsymbol{A}$ then $\boldsymbol{r}(\dot{\boldsymbol{x}}, \dot{\boldsymbol{y}})$ is a witness for $\varphi(\boldsymbol{x}) \in \boldsymbol{B}$.
(3) If $\dot{x}$ is a name of $\boldsymbol{x} \in \boldsymbol{X}$ and $\dot{z}$ is a name of $\varphi(x) \in \boldsymbol{B}$ then $\boldsymbol{\ell}(\dot{\boldsymbol{x}}, \dot{\boldsymbol{z}})$ is a witness for $\boldsymbol{x} \in \boldsymbol{A}$.

- $\varphi$ is a reduction for $\boldsymbol{A} \leq \boldsymbol{B}$ (on underlying sets)
- $r$ is a realizer for " $x \in A \Longrightarrow \varphi(x) \in B$ "
- $\ell$ is a realizer for " $x \in A \Longleftarrow \varphi(x) \in B$ "

## Theorem (Veldman 2008)

In a certain intuitionistic system,
$F I N=\left\{x \in \mathbb{N}^{\mathbb{N}}: \exists \boldsymbol{n} \forall m>\boldsymbol{n} . \boldsymbol{x}(\boldsymbol{m})=0\right\}$ is not $\Sigma_{2}^{0}$-complete.
This is because:

- The witness-search problem for FIN is not Levin-complete among the witness-search problems for $\Sigma_{2}^{\mathbf{0}}$ formulas even in classical mathematics.

## Theorem (Veldman 2022)

In a certain intuitionistic system, the set $\boldsymbol{I F}(\boldsymbol{K B})$ of trees which are ill-founded w.r.t. the Kleene-Brouwer ordering is not $\boldsymbol{\Sigma}_{1}^{\mathbf{1}}$-complete.

This is because:

- The witness-search problem for $\boldsymbol{I F}(\mathbf{K B})$ is not Levin-complete among the witness-search problems for $\Sigma_{1}^{1}$ formulas even in classical mathematics.
- Our observation shows that Veldman's seemingly strange results can also be understood by classical mathematicians as results regarding Levin reducibility for witness-search problems.
- However, simply interpreting previous results in a different context is of course not very interesting.
$\triangleright$ It is interesting when the interpretation leads to a truly new discovery.
- One of our new discoveries is that the "three layers" of $\boldsymbol{\Sigma}_{2}^{0}$ formulas w.r.t Levin reducibility (in classical mathematics).
$\Sigma_{2}^{0}$ subobject $\approx \Sigma_{2}^{0}$ subset with existential witnesses
Classification of $\boldsymbol{\Sigma}_{2}^{\mathbf{0}}$ formulas $\exists \boldsymbol{Z} \forall \boldsymbol{m} \varphi(\boldsymbol{n}, \boldsymbol{m})$ :
- (Unique Witness) " $\exists \boldsymbol{n} \forall m \varphi(n, m) \leftrightarrow \exists!\boldsymbol{n} \forall m \varphi(n, m) "$
- (Increasing Witness) " $k \leq n$ and $\forall m \varphi(k, m) \rightarrow \forall m \varphi(n, m)$ "

## Definition:

- A u.w. $\Sigma_{2}^{0}$ subobject is a subobject defined by a $\Sigma_{2}^{0}$ formula satisfying (Unique Witness).
- A i.w. $\Sigma_{2}^{0}$ subobject is a subobject defined by a $\boldsymbol{\Sigma}_{2}^{\mathbf{0}}$ formula satisfying (Increasing Witness).

Example:

- $F I N=\left\{x \in \mathbb{N}^{\mathbb{N}}: \exists n \forall m \geq n . x(m)=0\right\}$ is a u.w. $\Sigma_{2}^{0}$ subobj. of $\mathbb{N}^{\mathbb{N}}$.
- Bdd $=\left\{x \in \mathbb{N}^{\mathbb{N}}: \exists \boldsymbol{n} \forall m . x(\boldsymbol{m})<\boldsymbol{n}\right\}$ is an i.w. $\Sigma_{2}^{0}$ subobject of $\mathbb{N}^{\mathbb{N}}$.
- Every u.w. $\boldsymbol{\Sigma}_{2}^{\mathbf{0}}$ subobject is an i.w. $\boldsymbol{\Sigma}_{2}^{\mathbf{0}}$ subobject.

Classification of $\boldsymbol{\Sigma}_{2}^{\mathbf{0}}$ formulas $\exists \boldsymbol{Z} \forall \boldsymbol{m} \varphi(\boldsymbol{n}, \boldsymbol{m})$ :

- (Unique Witness) " $\boldsymbol{\exists} \boldsymbol{n} \forall \boldsymbol{m} \varphi(\boldsymbol{n}, \boldsymbol{m}) \leftrightarrow \exists!\boldsymbol{n} \forall \boldsymbol{m} \varphi(\boldsymbol{n}, \boldsymbol{m})$ "
- (Increasing Witness) " $k \leq n$ and $\forall m \varphi(k, m) \rightarrow \forall m \varphi(n, m)$ "

## Theorem

- FIN is Levin complete among u.w. $\boldsymbol{\Sigma}_{2}^{0}$ subobjects.
- Bdd is Levin complete among i.w. $\boldsymbol{\Sigma}_{2}^{0}$ subobjects.
- There is a Levin complete subobject among all $\Sigma_{2}^{\mathbf{0}}$ subobjects.
- They have different Levin reducibility degrees from each other.

- FIN is Levin complete among u.w. $\boldsymbol{\Sigma}_{2}^{0}$ subobjects.
- $\boldsymbol{B d} \boldsymbol{d}$ is Levin complete among i.w. $\boldsymbol{\Sigma}_{2}^{\mathbf{0}}$ subobjects.
- There is a Levin complete subobject among all $\boldsymbol{\Sigma}_{2}^{\mathbf{0}}$ subobjects.
